Description & Clinical Context

Does tCBT perform better in preventing the chances of developing CWP against usual intervention in patients with fibromyalgia?

Abstract / Protocol Summary

Background: Cognitive behavioural therapy (CBT) has been shown to improve outcomes for patients with fibromyalgia, and its cardinal feature chronic widespread pain (CWP). Prediction models have now been developed which identify groups who are at high-risk of developing CWP. It would be beneficial to be able to prevent the development of CWP in these people because of the high cost of symptoms and because once established they are difficult to manage. We will test the hypothesis that among patients who are identified as at high-risk, a short course of telephone-delivered CBT (tCBT) reduces the onset of CWP. We will further determine the cost-effectiveness of such a preventative intervention.

Methods: The study will be a two-arm randomised trial testing a course of tCBT against usual care for prevention of CWP. Eligible participants will be identified from a screening questionnaire sent to patients registered at general practices within three Scottish health boards. Those returning questionnaires indicating they have visited their doctor for regional pain in the last 6 months, and who have two of, sleep problems, maladaptive behaviour response to illness, or high number of somatic symptoms, will be invited to participate. After giving consent, participants will be randomly allocated to either tCBT or usual care. We aim to recruit 473 participants to each treatment arm. Participants in the tCBT group will have an initial assessment with a CBT therapist by telephone, then 6 weekly sessions, and booster sessions 3 and 6 months after treatment start. Those in the usual care group will receive no additional intervention. Follow-up questionnaires measuring the same items as the screening survey questionnaire will be sent 3, 12 and 24 months after start of treatment. The main outcome will be CWP at the 12 month questionnaire.

Discussion: This will be the first trial of an intervention aimed at preventing fibromyalgia or CWP. The results of the study will help to inform future treatments for the prevention of chronic pain, and aetiological models of its development.

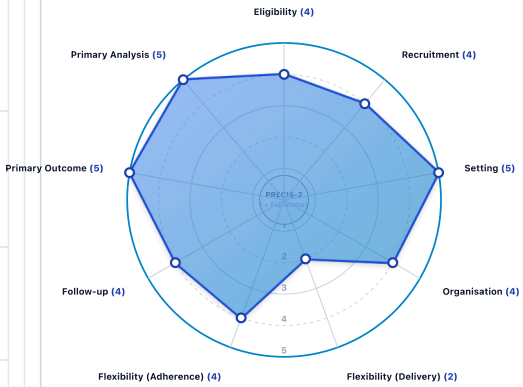

9 PRECIS-2 Domains & Scoring

Scores update wheel in real-time

DOMAIN	SCORE (1 TO 5)		JUSTIFICATION / RATIONALE
1. Eligibility	4	4: Rather Pragmatic	Taking into account the inclusion and exclusion criteria, the eligibility criteria wasn't too strict and external validity should be achievable
2. Recruitment	4	4: Rather Pragmatic	Since the patients were invited if they passed the screening, there wasn't any tedious extra effort needed to gather the participants
3. Setting	5	5: Very Pragmatic	The location of the trial isn't limited to a specific location since it's the intervention is done over the phone
4. Organisation	4	4: Rather Pragmatic	The only staff needed to perform the intervention were CBT therapist. The score 4 is given because the intervention can only be done by CBT therapist instead of the general clinicians
5. Flexibility (Delivery)	2	2: Rather Explanatory	The intervention delivery had to follow a specific set of procedure and schedule
6. Flexibility (Adherence)	4	4: Rather Pragmatic	Participant adherence weren't that strict since there aren't any major risks when delivering the intervention that may affect the participants likeliness to withdraw
7. Follow-up	4	4: Rather Pragmatic	The follow ups aren't that intense with 3 follow-ups in the form of a questionnaire.
8. Primary Outcome	5	5: Very Pragmatic	Since the primary outcome is to prevent the development of CWP through tCBT, this outcome can be directly felt by the patients
9. Primary Analysis	5	5: Very Pragmatic	Patient data with errors are still treated as valid but imputation is used to fix those errors
